Gastrointestinal tract and skin involvement are very rare and have been reported in less than 1% of cases of extrapulmonary TB. Gastrointestinal TB can affect any organ of the digestive tract, but peritonitis is the most common presentation. When the intestine is compromised the infection is localized at the ileocecal valve in 85% of cases.\(^4\) Anal TB is a very rare condition, occurring in less than 1% of intestinal TB and in less than 0.0015% of all cases of TB. In 2008, Mathew et al.\(^5\) described the case of an 80-year-old patient with anal TB and reported that only 3 cases have been published in the United Kingdom. Perianal TB is categorized as periorificial cutaneous tuberculosis or tuberculosis cutisificialis. It accounts for approximately 2% of cases of cutaneous tuberculosis. Tuberculosis cutisificialis results from self-inoculation of \textit{M. tuberculosis} into the periorificial oropharyngeal, anal, or genital mucosa from an initial pulmonary, intestinal, or genitourinary infection. Bacilli may reach the perianal area by hematogenous dissemination or by swallowing infected sputum. Numerous forms of anal TB have been described. The most common presentation is as an ulcerated lesion; fissures, verrucous forms, and masses have been reported in fewer cases. In 2009, Antonello et al.\(^6\) described the case of a 40-year-old HIV-positive patient with perianal TB that presented as an ulcerating mass, a compound lesion very similar to the finding in our patient. The patient presented by Cheon et al.\(^7\) in 2013 was a 46-year-old man diagnosed with Crohn disease 30 years earlier and treated with mesalazine with no improvement of his rectal ulcers. Anal TB was diagnosed and the patient presented a marked improvement after 3 months of treatment. Another case of anal TB was reported in a 42-year-old patient on Adalimumab therapy for psoriatic arthritis.\(^8\)

The treatment of anal TB is the same as for other forms of extrapulmonary TB. Patients should receive rifampicin, isoniazid, pyrazinamide, and ethambutol daily for 2 months, followed by rifampicin and isoniazid 3 times a week for 7 months (total treatment time, 9 months).\(^9\) In order to prevent the appearance of active tuberculosis, the Centers for Disease Control and Prevention advocates targeted screening and treatment of latent tuberculosis infection with 9 months of isoniazid. A newer regimen of weekly combined therapy with isoniazid and rifapentine for 12 weeks was cost-effective in directly observed therapy programs, particularly for populations that would not otherwise complete therapy and are at high risk for conversion to active disease, such as homeless patients.\(^10\)

**Cutaneous Sarcoid with Livedoid Changes in a Patient with Hashimoto’s Thyroiditis**

**Sarcoidosis cutánea con cambios livedoides en un paciente con tiroiditis de Hashimoto**

**Dear Editor:**

Association of sarcoidosis and autoimmune thyroiditis is rare. We report a case of cutaneous sarcoid surrounded by livedo on the lower extremities in a patient with Hashimoto’s thyroiditis.

A 72-year-old female visited the Department of Dermatology of Hoshi General Hospital, complaining of asymptomatic reddish eruptions on the lower extremities which appeared six months previously. She had Hashimoto’s thyroiditis for several years, but had been followed without medications. Physical examination showed multiple reddish, infiltrative round and irregular-shaped, up to 4-cm sized plaques on the anterior aspects of the bilateral thighs and lower legs (Fig. 1a). The erythematous plaques coalesced on the left thigh, and livedo was observed in the surroun-
Autoimmune thyroiditis is sometimes seen in association with sarcoidosis,\textsuperscript{1} and to date, several cases of co-occurrence of sarcoidosis and Hashimoto’s thyroiditis have been reported. Isernet et al.\textsuperscript{2} reported that 10 out of 348 patients with sarcoidosis had autoimmune thyroiditis, and sarcoidosis preceded autoimmune thyroiditis in 9 cases. The diagnosis of autoimmune thyroiditis was made when sarcoidosis was in remission. Papadopoulos et al.\textsuperscript{3} reported that 13 patients had thyroid autoimmunity (6 with Hashimoto’s thyroiditis, 2 with Graves’ disease and 5 with isolated positive thyroid serology) among a series of 78 patients with sarcoidosis. Nakamura et al.\textsuperscript{4} found 7 cases of Hashimoto’s thyroiditis in a series of 62 patients with pulmonary sarcoidosis. Unfortunately, an open biopsy of thyroid nodule was not carried out to differentiate thyroid sarcoidosis in the present case. At present, sarcoidal lesions were not detected in other organs, \textit{i.e.} lung or eyes. Moreover, a tuberculin test revealed positive reaction. Therefore, we consider that the patient developed cutaneous sarcoid only; however, we will carefully follow up this patient whether symptoms of systemic sarcoidosis will appear in the future.

Macrophages play an important role in sarcoidal granuloma formation \textit{via} several cytokines such as TNF-\(\alpha\) and IL-1\(\beta\). Several recent studies have reported the effectiveness of TNF-\(\alpha\) inhibition for sarcoidosis. Our studies showed a number of CD163-positive macrophages surrounding the degenerated collagen in the dermis. In addition, strong expression of IL-17 and TNF-\(\alpha\) was detected in the lesional skin of sarcoidosis. TNF-\(\alpha\) activates Th17 cells leading IL-17 production, and recent studies have shown that IL-17 was abundantly detected in sarcoidal lesions, suggesting that Th17 cells induce granuloma formation by suppressing regulatory T-cells.\textsuperscript{5} Recent findings suggest an important etiologic role of \textit{Propionibacterium acnes} (\textit{P. acnes}) in sar-
coidosis. *P. acnes* induces IL-17 and interferon-γ, and is thus implicated to play a pathogenic role in sarcoidosis via Th1/Th17 cytokines.

Finally, livedo was seen around sarcoidal plaques on the bilateral thigh. To date, only a few cases have been presented with livedo in association with sarcoidosis. A biopsy was taken from the sarcoidal plaque, but not from the surrounding livedo. However, histological examination showed granulomas around the vessels, which may induce livedo.
