can lead to confusion with other vasculitides, particularly with the ANCA-positive vasculitides (polyarteritis nodosa, microscopic polyangiitis, eosinophilic granulomatosis with polyangiitis, granulomatosis with polyangiitis). As no pathognomonic laboratory or histopathologic criteria exist, the diagnosis is purely clinical and is made by exclusion. A detailed clinical history and a high level of clinical suspicion are paramount.1-3,9

The diagnostic approach to cases of suspected cocaine-induced cutaneous vasculitis should include complete blood count, biochemistry including liver and kidney function tests, erythrocyte sedimentation rate, urinalysis, chest X-ray, fecal occult blood, full thickness skin biopsy, antiphospholipid antibodies, coagulation studies including homocysteine and proteins C and S, cryoglobulins, serum ANCA and ANA antibodies, double-stranded DNA antibodies, rheumatoid factor and complement levels, and serology for HIV, HBV, and HCV. Other tests such as blood, urine, or skin microbiology should be performed as required.1,3,4

The skin lesions usually resolve within 2–3 weeks after cessation of cocaine use. Normalization of laboratory tests can take 2–14 months, though the neutropenia recovers fully in less than 10 days.1,1,5,7,8

There is no consensus regarding treatment of this condition. Obviously, removal of the cause is the most important measure, together with symptom relief. Good clinical outcomes have been reported with the use of nonsteroidal anti-inflammatory drugs for arthralgia and colchicine, dapsone, oral antithiamines, and pentoxifylline for the skin lesions.1,3,4 Systemic corticosteroids have not been shown to be effective.

Father-to-Newborn Transmission of Herpes Simplex Virus Infection: A Sweet but Bitter Kiss

Herpes neonatal tras contacto con herpes labial paterno: dulce y amargo beso

Dear Editor,

While rare, neonatal herpes simplex virus (HSV) infection is one of the most severe perinatal infections. Only 10% of cases are acquired after birth. The disease is classified according to clinical presentation as follows: skin, eye, and mouth (SEM) disease (prevalence of ≈45%); central nervous system (CNS) disease (≈30%), and disseminated disease (≈25%), which has the worst prognosis.1 No deaths have been reported for SEM disease, but 2% of those affected may develop some degree of impairment by the age of 12 years.2 Early recognition and treatment with high-dose acyclovir (60 mg/kg/d) reduces mortality and may improve long-term outcomes.3

We present the case of a 10-day-old newborn female admitted to the hospital with generalized skin lesions that had appeared 5 h previously. The lesions consisted of groups of vesicles and pustules overlying erythematous skin, affecting the trunk and tongue (Fig. 1). The infant did not have fever or neurologic symptoms and was systemically well. There had been no complications during the pregnancy, vaginal delivery, or immediate postpartum period. The mother had had systemic lupus erythematosus for the past 6 years, but this was clinically stable. She had had chickenpox during her childhood but had no genital lesions suggestive of herpes
HSV type 1 has increased in the last decade, possibly as a consequence of changing sexual habits among parents. An early diagnosis is mandatory and the method of choice is detection of HSV DNA by PCR or virus culture.

Our findings led to a diagnosis of neonatal HSV type 1 infection (SEM disease). We believe that the most likely source of transmission was the father’s herpes simplex labialis, although we cannot be entirely certain because virus isolation was not performed. We initiated early empirical treatment about 8h after onset of the lesions, and may, therefore, have prevented progression to CNS involvement.

The aim of this article is to alert dermatologists to the possibility of postnatally acquired HSV infection in newborns. We emphasize the importance of establishing an early diagnosis and initiating empirical treatment upon the first suspicion. Based on our case, we strongly recommend separation of the newborn from any person with active HSV lesions (mothers with herpes labialis should wear a mask). We also recommend offering anticipatory guidance for parents.

Conflict of interests

The authors declare no conflict of interest.

Acknowledgments

We thank the patient’s parents for providing the photographs used in this article and for authorizing their publication. We would also like to thank Rabia Sofia Rashid for correcting the manuscript.
